Symbolic Weighted Language Models and Quantitative Parsing over Infinite Alphabets

Florent Jacquemard ✉ ⌂ iD

Inria & CNAM, Paris, France

— Abstract

We propose a framework for weighted parsing over infinite alphabets. It is based on language models called Symbolic Weighted Automata (swA) at the joint between Symbolic Automata (sA) and Weighted Automata (wA), as well as Transducers (swT) and Visibly Pushdown (sw-VPA) variants. Like sA, swA deal with large or infinite input alphabets, and like wA, they output a weight value in a semiring domain. The transitions of swA are labeled by functions from an infinite alphabet into the weight domain. This is unlike sA whose transitions are guarded by boolean predicates overs symbols in an infinite alphabet and also unlike wA whose transitions are labeled by constant weight values, and who deal only with finite automata. We present some properties of swA, swT and sw-VPA models, that we use to define and solve a variant of parsing over infinite alphabets. We also briefly describe the application that motivated the introduction of these models: a parse-based approach to automated music transcription.
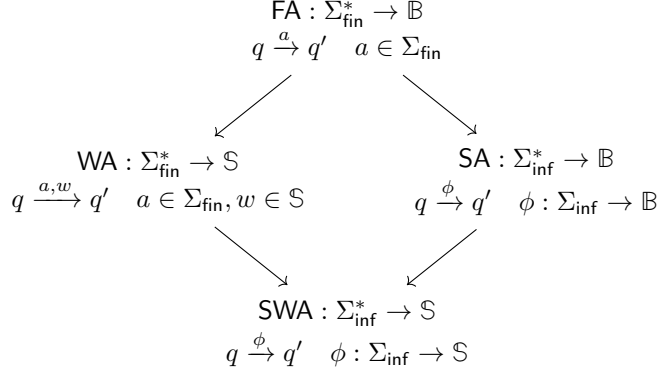

1 Introduction

Parsing is the problem of structuring a linear representation on input (a finite word), according to a language model. Most of the context-free parsing approaches [15] assume a finite and reasonably small input alphabet. Such a restriction makes perfect sense in the context of NLP tasks such as constituency parsing, or of programming languages compilers or interpreters. Considering large or infinite alphabets can however be of practical interest, for instance, when dealing with large characters encodings such as UTF-16, *e.g.* for vulnerability detection in Web-applications [8], for the analyse (*e.g.* validation or filtering) of data streams or serialization of structured documents (with textual or numerical attributes) [26], or for processing timed execution traces [3]. The latter case is related to a study that motivated the present work: automated music transcription. In this problem, a music performance, represented symbolically in the form of a sequence of timed musical events, is converted into a score in Common Western Music Notation [14], structured according to nested grouping and metric strength of events. It can therefore be stated as a parsing problem [12], over an infinite alphabet of timed events.

Various extensions of language models for handling infinite alphabets have been studied. For instance, some automata with memory extensions allow restricted storage and comparison of input symbols, (see [26] for a survey), with pebbles for marking positions [25], registers [18], or the possibility to compute on subsequences with the same attribute values [2]. The automata at the core of model checkers compute on input symbols represented by large bitvectors [27] (sets of assignments of Boolean variables) and in practice, each transition accepts a set of such symbols (instead of an individual symbol), represented by Boolean

> I think that we can make the case for a larger set of situations: given a linear music notation input, for instance elements in an XML file, we we want to structure the input according to a hierarchical rhythmic space. I can elaborate...

$$q \xrightarrow{\phi} q' \quad \phi : \Sigma_{\mathsf{inf}} \to \mathbb{B}$$

$$\mathsf{SWA} : \Sigma_{\mathsf{inf}}^* \to \mathbb{S}$$
$$q \xrightarrow{\phi} q' \quad \phi : \Sigma_{\mathsf{inf}} \to \mathbb{S}$$

Figure 1 Classes of Symbolic/Weighted Automata. Σ_{fin} is a finite alphabet, Σ_{inf} is a countable alphabet, $\mathbb{B}$ is the Boolean algebra, $\mathbb{S}$ is a commutative semiring, $q \xrightarrow{\cdots} q'$ is a transition between states q and q'.

formula or Binary Decision Diagrams. Following a similar idea, in symbolic automata (sA) [7, 8], the transitions are guarded by predicates over infinite alphabet domains. With appropriate closure conditions on the sets of such predicates, all the good properties enjoyed by automata over finite alphabets are preserved.

Other extensions of language models help in dealing with non-determinism, by the computation of weight values. With an ambiguous grammar, there may exist several derivations (*abstract syntax trees* – AST) yielding one input word. The association of one weight value to each AST permits to select a best one (or n bests). This is roughly the principle of *weighted parsing* approaches [13, 24, 23]. In *weighted language models*, like *e.g.* probabilistic context-free grammars and weighted automata (wA) [11], a weight value is associated to each transition rule, and the rule's weights can be combined with a associative product operator $\otimes$ into the weight of an AST. A second operator $\oplus$, associative and commutative, is moreover used to handle the ambiguity of the model, by summing the weights of the possibly several (in general exponentially many) AST associated to a given input word. Typically, $\oplus$ will select the best of two weight values. The weight domain, equipped with these two operators shall be, at minima, a *semiring* where $\oplus$ can be extended to infinite sums, such as the Viterbi semiring and the tropical min-plus algebra, see Figure 2.

In this paper, we present a uniform framework for weighted parsing over infinite input alphabets. It is based on *symbolic weighted* finite states language models (swM), generalizing sA, with functions into an arbitrary semiring instead of Boolean guards, and wA, by handling infinite alphabets, see Figure 1. In the transition rules of swM models, input symbols appear as variables, and the weight associated to a transition rule is a function of these variables. The models presented here are finite automata called symbolic-weighted (swA), transducers (swT), and pushdown automata with a visibly restriction [1] (sw-VPA). The latter model of automata operates on *nested words* [1], a structured form of words parenthesized with markup symbols, corresponding to a linearization of trees. In the context of parsing, they can represent (weighted) AST of CF grammars. More precisely, a sw-VPA A associates a weight value $A(t)$ to a given nested word t, which is the linearization of an AST. On the other hand, a swT can define a distance $T(s,t)$ between finite words s and t over infinite alphabets. Then, the *SW-parsing* problem aims at finding t minimizing $T(s,t) \otimes A(t)$ (*wrt* the ranking defined by $\oplus$), given an input word s. The latter value is called the distance between s and A in [21]. Like weighted-parsing methods [13, 24, 23], our approach proceeds

This sentence (symbols as variables) is not immediately clear to me. Maybe a short example or intuition?

The weight is a label on edges in the derivation tree, right? Not sure I understand the sentence

You mean the distance between s and t? "The latter value" is a bit ambiguous

in two steps, based on properties of the swM. The first step is an intersection (Bar-Hillel construction [15]) where, given a swT T, a sw-VPA A, and an input word s, a sw-VPA $A_{T,s}$ is built, such that for all t, $A_{T,s}(t) = T(s,t) \otimes A(t)$. In the second step, a best AST t is found by applying to $A_{T,s}$ a best search algorithm similar to the shortest distance in graphs [20, 17].

The main contributions of the paper are: (i) the introduction of automata, swA, transducers, swT (Section 3), and visibly pushdown automata sw-VPA (Section 4), generalizing the corresponding classes of symbolic and weighted models, (ii) a polynomial best-search algorithm for sw-VPA, and (iii) a uniform framework (Section 5) for parsing over infinite alphabets, the keys to which are ($iii.a$) the swT-based definition of generic edit distances between input and output (yield) words, and ($iii.b$) the use, convenient in this context, of nested words, and sw-VPA, instead of syntax trees and grammars.

2   Preliminary Notions

Semirings

We shall consider semirings for the weight values of our language models. . A *semiring* $\langle \mathbb{S}, \oplus, \mathbb{0}, \otimes, \mathbb{1} \rangle$ is a structure with a domain $\mathbb{S}$, equipped with two associative binary operators $\oplus$ and $\otimes$, with respective neutral elements $\mathbb{0}$ and $\mathbb{1}$, and such that:

- $\oplus$ is commutative: $\langle \mathbb{S}, \oplus, \mathbb{0} \rangle$ is a commutative monoid and $\langle \mathbb{S}, \otimes, \mathbb{1} \rangle$ a monoid,
- $\otimes$ distributes over $\oplus$: $\forall x, y, z \in \mathbb{S}$, $x \otimes (y \oplus z) = (x \otimes y) \oplus (x \otimes z)$, and $(x \oplus y) \otimes z = (x \otimes z) \oplus (y \otimes z)$,
- $\mathbb{0}$ is absorbing for $\otimes$: $\forall x \in \mathbb{S}$, $\mathbb{0} \otimes x = x \otimes \mathbb{0} = \mathbb{0}$.

Intuitively, in the models presented in this paper, $\oplus$ selects an optimal value from two given values, in order to handle non-determinism, and $\otimes$ combines two values into a single value, in a chaining of transitions.

A semiring $\mathbb{S}$ is *commutative* if $\otimes$ is commutative. It is *idempotent* if for all $x \in \mathbb{S}$, $x \oplus x = x$. Every idempotent semiring $\mathbb{S}$ induces a partial ordering $\leq_\oplus$ called the *natural ordering* of $\mathbb{S}$ [20] defined, by: for all $x, y \in \mathbb{S}$, $x \leq_\oplus y$ iff $x \oplus y = x$. The natural ordering is sometimes defined in the opposite direction [10]; We follow here the direction that coincides with the usual ordering on the Tropical semiring *min-plus* (Figure 2). An idempotent semiring $\mathbb{S}$ is called *total* if it $\leq_\oplus$ is total *i.e.* when for all $x, y \in \mathbb{S}$, either $x \oplus y = x$ or $x \oplus y = y$.

▶ **Lemma 1** (Monotony, [20]). *Let $\langle \mathbb{S}, \oplus, \mathbb{0}, \otimes, \mathbb{1} \rangle$ be an idempotent semiring. For all $x, y, z \in \mathbb{S}$, if $x \leq_\oplus y$ then $x \oplus z \leq_\oplus y \oplus z$, $x \otimes z \leq_\oplus y \otimes z$ and $z \otimes x \leq_\oplus z \otimes y$.*

To express the property of Lemma 1, we call $\mathbb{S}$ *monotonic wrt* $\leq_\oplus$. Another important semiring property in the context of optimization is superiority [16], which corresponds to the *non-negative weights* condition in shortest-path algorithms [9]. Intuitively, it means that combining elements with $\otimes$ always increase their weight. Formally, it is defined as the property (i) below.

▶ **Lemma 2** (Superiority, Boundedness). *Let $\langle \mathbb{S}, \oplus, \mathbb{0}, \otimes, \mathbb{1} \rangle$ be an idempotent semiring. The two following statements are equivalent:*
i. for all $x, y \in \mathbb{S}$, $x \leq_\oplus x \otimes y$ and $y \leq_\oplus x \otimes y$
ii. for all $x \in \mathbb{S}$, $\mathbb{1} \oplus x = \mathbb{1}$.

Proof. (ii) $\Rightarrow$ (i) : $x \oplus (x \otimes y) = x \otimes (\mathbb{1} \oplus y) = x$, by distributivity of $\otimes$ over $\oplus$. Hence $x \leq_\oplus x \otimes y$. Similarly, $y \oplus (x \otimes y) = (\mathbb{1} \oplus x) \otimes y = y$, hence $y \leq_\oplus x \otimes y$. ($i$) $\Rightarrow$ (ii) : by the second inequality of (i), with $y = \mathbb{1}$, $\mathbb{1} \leq_\oplus x \otimes \mathbb{1} = x$, *i.e.*, by definition of $\leq_\oplus$, $\mathbb{1} \oplus x = \mathbb{1}$. ◀

[chap. intersection in [15]]

[The notation $A_{T,s}$ has not been introduced so far. It is not clear why T is a parameter there]

[OK, à quelques détails (pour moi), tout ça est très bien expliqué]

[expressiveness: VPA have restricted equality test. comparable to pebble automata? → conclusion]

[The results are established for a general class of semirings. They can be instantiated for concrete cases]

[There is sometimes a confusion in the text between the struture and the domain $\mathbb{S}$. Not essential]

[is total necessary?]

	domain	$\oplus$	$\otimes$	$\mathbb{0}$	$\mathbb{1}$
Boolean	$\{\bot, \top\}$	$\vee$	$\wedge$	$\bot$	$\top$
Counting	$\mathbb{N}$	$+$	$\times$	0	1
Viterbi	$[0,1] \subset \mathbb{R}$	max	$\times$	0	1
Tropical min-plus	$\mathbb{R}_+ \cup \{\infty\}$	min	$+$	∞	0

Figure 2 Some commutative, bounded, total and complete semirings.

In [16], when the property (*i*) holds, $\mathbb{S}$ is called *superior wrt* the ordering $\leq_\oplus$. We have seen in the proof of Lemma 2 that it implies that $\mathbb{1} \leq_\oplus x$ for all $x \in \mathbb{S}$. Similarly, by the first inequality of (*i*) with $y = \mathbb{0}$, $x \leq_\oplus x \otimes \mathbb{0} = \mathbb{0}$. Hence, in a superior semiring, it holds that for all $x \in \mathbb{S}$, $\mathbb{1} \leq_\oplus x \leq_\oplus \mathbb{0}$. Intuitively, from an optimization point of view, it means that $\mathbb{1}$ is the best value, and $\mathbb{0}$ the worst. In [20], $\mathbb{S}$ with the property (*ii*) of Lemma 2 is called *bounded* – we shall use this term in the rest of the paper. It implies that, when looking for a best path in a graph whose edges are weighted by values of $\mathbb{S}$, the loops can be safely avoided, because, for all $x \in \mathbb{S}$ and $n \geq 1$, $x \oplus x^n = x \otimes (\mathbb{1} \oplus x^{n-1}) = x$.

▶ **Lemma 3.** *Every bounded semiring is idempotent.*

Proof. By boundedness, $\mathbb{1} \oplus \mathbb{1} = \mathbb{1}$, and idempotency follows by multiplying both sides by x and distributing. ◀

> Here the difference between $\mathbb{S}$ as a structure and as a domain is blurred.

We shall need below infinite sums with $\oplus$. A semiring $\mathbb{S}$ is called *complete* [11] if it has an operation $\bigoplus_{i \in I} x_i$ for every family $(x_i)_{i \in I}$ of elements of $dom(\mathbb{S})$ over an index set $I \subset \mathbb{N}$, such that:

> $j \in \mathbb{N}$: j is en element of $\mathbb{N}$, not the same s $j \subset \mathbb{N}$

i. *infinite sums extend finite sums:*
$$\bigoplus_{i \in \emptyset} x_i = \mathbb{0}, \quad \forall j \in \mathbb{N}, \bigoplus_{i \in \{j\}} x_i = x_j, \forall j, k \in \mathbb{N}, j \neq k, \bigoplus_{i \in \{j,k\}} x_i = x_j \oplus x_k,$$

ii. *associativity and commutativity:*
for all $I \subseteq \mathbb{N}$ and all partition $(I_j)_{j \in J}$ of I, $\bigoplus_{j \in J} \bigoplus_{i \in I_j} x_i = \bigoplus_{i \in I} x_i$,

iii. *distributivity of product over infinite sum:*
for all $I \subseteq \mathbb{N}$, $\bigoplus_{i \in I} (x \otimes y_i) = x \otimes \bigoplus_{i \in I} y_i$, and $\bigoplus_{i \in I} (x_i \otimes y) = (\bigoplus_{i \in I} x_i) \otimes y$.

> results of this paper for semirings commutative, bounded, total and complete

Label Theory

We shall now define the functions labeling the transitions of SW automata and transducers, generalizing the Boolean algebras of [7] from Boolean to other semiring domains. We consider *alphabets*, which are countable sets of symbols denoted Σ, Δ,... Given a semiring $\langle \mathbb{S}, \oplus, \mathbb{0}, \otimes, \mathbb{1} \rangle$, a *label theory* over $\mathbb{S}$ is a set $\bar{\Phi}$ of recursively enumerable sets denoted Φ_Σ, containing unary functions of type $\Sigma \to \mathbb{S}$, or $\Phi_{\Sigma,\Delta}$, containing binary functions $\Sigma \times \Delta \to \mathbb{S}$, and such that:

> OK, donc c'est là que les fonctions d'étiquettes prennent en argument l'input de la règle. Je ne sais pas dans quelle mesure il faut donner un peu d'explications pour faciliter la compréhension du formalisme.

– for all $\Phi_{\Sigma,\Delta} \in \bar{\Phi}$, we have $\Phi_\Sigma \in \bar{\Phi}$ and $\Phi_\Delta \in \bar{\Phi}$

– every $\Phi_\Sigma \in \bar{\Phi}$ contains all the constant functions from Σ into $\mathbb{S}$,

– for all $\alpha \in \mathbb{S}$ and $\phi \in \Phi_\Sigma$, $\alpha \otimes \phi : x \mapsto \alpha \otimes \phi(x)$, and $\phi \otimes \alpha : x \mapsto \phi(x) \otimes \alpha$

   belong to Φ_Σ, and similarly for $\oplus$ and for $\Phi_{\Sigma,\Delta}$

– for all $\phi, \phi' \in \Phi_\Sigma$, $\phi \otimes \phi' : x \mapsto \phi(x) \otimes \phi'(x)$ belongs to Φ_Σ

– for all $\eta, \eta' \in \Phi_{\Sigma,\Delta}$ $\eta \otimes \eta' : x, y \mapsto \eta(x,y) \otimes \eta'(x,y)$ belongs to $\Phi_{\Sigma,\Delta}$

– for all $\phi \in \Phi_\Sigma$ and $\eta \in \Phi_{\Sigma,\Delta}$, $\phi \otimes_1 \eta : x,y \mapsto \phi(x) \otimes \eta(x,y)$ and

$\eta \otimes_1 \phi : x,y \mapsto \eta(x,y) \otimes \phi(x)$ belong to $\Phi_{\Sigma,\Delta}$

– for all $\psi \in \Phi_\Delta$ and $\eta \in \Phi_{\Sigma,\Delta}$, $\psi \otimes_2 \eta : x,y \mapsto \psi(y) \otimes \eta(x,y)$ and

$\eta \otimes_2 \psi : x,y \mapsto \eta(x,y) \otimes \psi(y)$ belong to $\Phi_{\Sigma,\Delta}$

– similar closures hold for $\oplus$.

Intuitively, the operators $\bigoplus_\Sigma$ return global minimum, *wrt* $\leq_\oplus$, of functions of Φ_Σ. When the semiring $\mathbb{S}$ is complete, we consider the following operators on the functions of $\bar{\Phi}$.

$$\bigoplus_\Sigma : \Phi_\Sigma \to \mathbb{S}, \; \phi \mapsto \bigoplus_{a \in \Sigma} \phi(a)$$

$$\bigoplus_\Sigma^1 : \Phi_{\Sigma,\Delta} \to \Phi_\Delta, \; \eta \mapsto \big(y \mapsto \bigoplus_{a \in \Sigma} \eta(a,y)\big) \quad \bigoplus_\Delta^2 : \Phi_{\Sigma,\Delta} \to \Phi_\Sigma, \; \eta \mapsto \big(x \mapsto \bigoplus_{b \in \Delta} \eta(x,b)\big)$$

In what follows, we might omit the sub- and superscripts in $\otimes_1$, $\bigoplus_\Sigma^1$..., when there is no

ambiguity. We shall keep them only for the special case $\Sigma = \Delta$, *i.e.* $\eta \in \Phi_{\Sigma,\Sigma}$, in order to be able to distinguish between the first and the second argument.

▶ **Definition 4.** *A label theory $\bar{\Phi}$ is* complete *when the underlying semiring $\mathbb{S}$ is complete, and for all $\Phi_{\Sigma,\Delta} \in \bar{\Phi}$ and all $\eta \in \Phi_{\Sigma,\Delta}$, $\bigoplus_\Sigma^1 \eta \in \Phi_\Delta$ and $\bigoplus_\Delta^2 \eta \in \Phi_\Sigma$.*

The following facts are immediate.

▶ **Lemma 5.** *For $\bar{\Phi}$ complete $\alpha \in \mathbb{S}$, $\phi, \phi' \in \Phi_\Sigma$, $\psi \in \Phi_\Delta$, and $\eta \in \Phi_{\Sigma,\Delta}$:*

  i. $\bigoplus_\Sigma \bigoplus_\Delta^2 \eta = \bigoplus_\Delta \bigoplus_\Sigma^1 \eta$

  ii. $\alpha \otimes \bigoplus_\Sigma \phi = \bigoplus_\Sigma (\alpha \otimes \phi)$ *and* $(\bigoplus_\Sigma \phi) \otimes \alpha = \bigoplus_\Sigma (\phi \otimes \alpha)$, *and similarly for* $\oplus$

  iii. $(\bigoplus_\Sigma \phi) \oplus (\bigoplus_\Sigma \phi') = \bigoplus_\Sigma (\phi \oplus \phi')$ *and* $(\bigoplus_\Sigma \phi) \otimes (\bigoplus_\Sigma \phi') = \bigoplus_\Sigma (\phi \otimes \phi')$

  iv. $(\bigoplus_\Delta^2 \eta) \oplus (\bigoplus_\Delta^2 \eta') = \bigoplus_\Delta^2 (\eta \oplus \eta')$, *and* $(\bigoplus_\Delta^2 \eta) \otimes (\bigoplus_\Delta^2 \eta') = \bigoplus_\Delta^2 (\eta \otimes \eta')$

  v. $\phi \otimes (\bigoplus_\Delta^2 \eta) = \bigoplus_\Delta (\phi \otimes_1 \eta)$, *and* $(\bigoplus_\Delta^2 \eta) \otimes \phi = \bigoplus_\Delta (\eta \otimes_1 \phi)$, *and similarly for* $\oplus$

  vi. $\psi \otimes (\bigoplus_\Sigma^1 \eta) = \bigoplus_\Sigma (\psi \otimes_2 \eta)$, *and* $(\bigoplus_\Sigma^1 \eta) \otimes \psi = \bigoplus_\Sigma (\eta \otimes_2 \psi)$, *and similarly for* $\oplus$

A label theory is called *effective* when for all $\phi \in \Phi_\Sigma$ and $\eta \in \Phi_{\Sigma,\Delta}$, $\bigoplus_\Sigma \phi$, $\bigoplus_\Delta \bigoplus_\Sigma \eta$, and $\bigoplus_\Sigma \bigoplus_\Delta \eta$ can be effectively computed from ϕ and η.

Concretely, in one of the language models defined below, we consider a finite number of base functions ϕ, η of the underlying label theory, labelling transitions, and combine them with the above operators for construction of other models. The combinations might be represented by dags (diagrams) whose leaves are labeled by base functions and inner nodes by operators.

3 SW Automata and Transducers

We follow the approach of [21] for the computation of distances, between words and languages, using weighted transducers, and extend it to infinite alphabets. The models introduced in this section generalize weighted automata and transducers [11] by labeling each transition with a weight function (instead of a simple weight value), that takes the input and output symbols as parameters. These functions are similar to the guards of symbolic automata [7, 8], but they can return values in a generic semiring, whereas the latter guards are restricted to the Boolean semiring.

Let $\mathbb{S}$ be a commutative semiring, Σ and Δ be alphabets called respectively *input* and *output*, and $\bar{\Phi}$ be a label theory over $\mathbb{S}$ containing Φ_Σ, Φ_Δ, $\Phi_{\Sigma,\Delta}$.

196 ▶ **Definition 6.** *A symbolic-weighted transducer (swT) over* Σ, Δ, $\mathbb{S}$ *and* $\bar{\Phi}$ *is a tuple*
197 $T = \langle Q, \mathsf{in}, \bar{\mathsf{w}}, \mathsf{out} \rangle$, *where Q is a finite set of states,* $\mathsf{in} : Q \to \mathbb{S}$ *(respectively* $\mathsf{out} : Q \to \mathbb{S}$*)*
198 *are functions defining the weight for entering (respectively leaving) computation in a state,*
199 *and* $\bar{\mathsf{w}}$ *is a triplet of transition functions* $\mathsf{w}_{10} : Q \times Q \to \Phi_\Sigma$, $\mathsf{w}_{01} : Q \times Q \to \Phi_\Delta$, *and*
200 $\mathsf{w}_{11} : Q \times Q \to \Phi_{\Sigma,\Delta}$.

201 We call *number of transitions* of T the number of pairs of states $q, q' \in Q$ such that w_{10} or
202 w_{01} or w_{11} is not the constant $\mathbb{0}$. For convenience, we shall sometimes present transitions as

<div style="border:1px solid green;color:green;">I missed sth: what 203 is this ε? Intuitively clear but not 204 defined?</div>

203 functions of $Q \times (\Sigma \cup \{\varepsilon\}) \times (\Delta \cup \{\varepsilon\}) \times Q \to \mathbb{S}$, overloading the function names, such that,
204 for all $q, q' \in Q$, $a \in \Sigma$, $b \in \Delta$,

205
$$
\begin{aligned}
\mathsf{w}_{10}(q, a, \varepsilon, q') &= \phi(a) && \text{where } \phi = \mathsf{w}_{10}(q, q') \in \Phi_\Sigma, \\
\mathsf{w}_{01}(q, \varepsilon, b, q') &= \psi(b) && \text{where } \psi = \mathsf{w}_{01}(q, q') \in \Phi_\Delta, \\
\mathsf{w}_{11}(q, a, b, q') &= \eta(a, b) && \text{where } \eta = \mathsf{w}_{11}(q, q') \in \Phi_{\Sigma,\Delta}.
\end{aligned}
$$

206 The swT T computes on pairs of words $\langle s, t \rangle \in \Sigma^* \times \Delta^*$, s and t, being respectively called
207 *input* and *output* word. More precisely, T defines a mapping from $\Sigma^* \times \Delta^*$ into $\mathbb{S}$, based on
208 an intermediate function weight_T defined recursively, for every states $q, q' \in Q$, and every
209 pairs of strings $\langle s, t \rangle \in \Sigma^* \times \Delta^*$, where au, and bv, denote the concatenation of the symbol

<div style="border:1px solid red;color:red;">added u and v def 210</div>

210 $a \in \Sigma$ (resp. $b \in \Delta$) with a word $u \in \Sigma^*$ (resp. $v \in \Delta^*$).

211
$$\mathsf{weight}_T(q, \varepsilon, \varepsilon, q') = \mathbb{1} \quad \text{if } q = q' \text{ and } \mathbb{0} \text{ otherwise} \tag{1}$$

212
$$\mathsf{weight}_T(q, s, t, q') = \bigoplus_{\substack{q'' \in Q \\ s=au,\, a\in\Sigma}} \mathsf{w}_{10}(q, a, \varepsilon, q'') \otimes \mathsf{weight}_T(q'', u, t, q')$$

213
$$\oplus \bigoplus_{\substack{q'' \in Q \\ t=bv,\, b\in\Delta}} \mathsf{w}_{01}(q, \varepsilon, b, q'') \otimes \mathsf{weight}_T(q'', s, v, q')$$

214
$$\oplus \bigoplus_{\substack{q'' \in Q \\ s=au,\, t=bv}} \mathsf{w}_{11}(q, a, b, q'') \otimes \mathsf{weight}_T(q'', u, v, q')$$

215

<div style="border:1px solid green;color:green;">OK tout ça se lit 216 bien :-)</div>

216 We recall that, by convention (Section 2), an empty sum with $\bigoplus$ is equal to $\mathbb{0}$. Intuitively,
217 using a transition $\mathsf{w}_{ij}(q, a, b, q')$ means for T: when reading respectively a and b at the current
218 positions in the input and output words, increment the current position in the input word if
219 and only if $i = 1$, and in the output word iff $j = 1$, and change state from q to q'. When
220 $a = \varepsilon$ (resp. $b = \varepsilon$), the current symbol in the input (resp. output) is not read. Since $\mathbb{0}$
221 is absorbing for $\otimes$ in $\mathbb{S}$, one term $\mathsf{w}_{ij}(q, a, b, q'')$ equal to $\mathbb{0}$ in the above expression will be
222 ignored in the sum, meaning that there is no possible transition from state q into state q'
223 while reading a and b. This is analogous to the case of a transition's guard not satisfied by
224 $\langle a, b \rangle$ for symbolic transducers.

225 The expression (1) can be seen as a stateful definition of an edit-distance between a
226 word $s \in \Sigma^*$ and a word $t \in \Delta^*$, see also [22]. Intuitively, $\mathsf{w}_{10}(q, a, \varepsilon, r)$ is the cost of the
227 deletion of the symbol $a \in \Sigma$ in s, $\mathsf{w}_{01}(q, \varepsilon, b, r)$ is the cost of the insertion of $b \in \Delta$ in t, and
228 $\mathsf{w}_{11}(q, a, b, r)$ is the cost of the substitution of $a \in \Sigma$ by $b \in \Delta$. The cost of a sequence of
229 such operations transforming s into t, is the product, with $\otimes$, of the individual costs of the
230 operations involved; and the distance between s and t is the sum, with $\oplus$, of all possible
231 products. Formally, the weight associated by T to $\langle s, t \rangle \in \Sigma^* \times \Delta^*$ is:
$$T(s,t) = \bigoplus_{q,q' \in Q} \mathsf{in}(q) \otimes \mathsf{weight}_T(q,s,t,q') \otimes \mathsf{out}(q') \tag{2}$$

▶ **Example 7.** In Common Western Music Notation [14], several symbols may be used to represent one single sounding event. For instance, several notes can be combined with a tie, like in ♩ ♪, and one note can be augmented by half its duration with a dot like in ♩.. These notations are perceived equivalent when played, as their duration is equal, yet the notation is different. We thus want to be able to compare a music score with music played by a performer. We propose a small weighted transducer model that calculates the distance bewteen an input sequence of sounding events (music "performance") to an output sequence of written events (music "score"). Let us consider the tropical (*min-plus*) semiring $\mathbb{S}$ of Figure 2 and let $\Sigma = \mathbb{R}_+$ be an input alphabet of event dates and $\Delta = \{\mathsf{e}, -\} \times \mathbb{R}_+$ be an output alphabet of symbols with timestamps. A symbol $\langle \mathsf{e}, d \rangle \in \Delta$ represents an event starting at date d, and $\langle -, d \rangle$ is a continuation of the previous event.

We consider a swT with two states q_0 and q_1 whose purpose is to compare a recorded performance $s \in \Sigma^*$ with a notated music sheet $t \in \Delta^*$. One timestamp $d_i \in \Sigma$ may correspond to one notated event $\langle \mathsf{e}, d_i' \rangle \in \Delta$, in which case the weight value computed by the swT is the time distance between both (see transitions w_{11} below). If $\langle \mathsf{e}, d_i' \rangle$ is followed by continuations $\langle -, d_{i+1}' \rangle...$, they are just skipped with no cost (transitions w_{01} or weight $\mathbb{1}$).

$$
\begin{array}{rclcrcl}
\mathsf{w}_{11}(q_0, d, \langle \mathsf{e}, d' \rangle, q_0) & = & |d' - d| & \quad & \mathsf{w}_{11}(q_1, d, \langle \mathsf{e}, d' \rangle, q_0) & = & |d' - d| \\
\mathsf{w}_{01}(q_0, \varepsilon, \langle -, d' \rangle, q_0) & = & \mathbb{1} & \quad & \mathsf{w}_{01}(q_1, \varepsilon, \langle -, d' \rangle, q_0) & = & \mathbb{1} \\
\mathsf{w}_{10}(q_0, d, \varepsilon, q_1) & = & \alpha & & & &
\end{array}
$$

We also must be able to take performing errors into account, while still being able to compare with the score, since a performer could, for example, play an unwritten extra note. This is modelled by the transition w_{10} with an arbitrary weight value $\alpha \in \mathbb{S}$, switching from state q_0 (normal) to q_1 (error). The transitions in the second column below switch back to the normal state q_0. At last, we let q_0 be the only initial and final state, with $\mathsf{in}(q_0) = \mathsf{out}(q_0) = \mathbb{1}$, and $\mathsf{in}(q_1) = \mathsf{out}(q_1) = \mathbb{0}$.

That way, an swT is capable of evaluating the differences between a score and a performance, all the while ensuring that performance errors are plausible.

◇

The *Symbolic Weighted Automata* are defined similarly as the transducers of Definition 6, by simply omitting the output symbols.

▶ **Definition 8.** *A symbolic-weighted automaton (swA) over Σ, $\mathbb{S}$ and $\bar{\Phi}$ is a tuple $A = \langle Q, \mathsf{in}, \mathsf{w}_1, \mathsf{out} \rangle$, where Q is a finite set of states, $\mathsf{in} : Q \to \mathbb{S}$ (respectively $\mathsf{out} : Q \to \mathbb{S}$) are functions defining the weight for entering (respectively leaving) computation in a state, and w_1 is a transition function from $Q \times Q$ into Φ_Σ.*

As above in the case of swT, when $\mathsf{w}_1(q, q') = \phi \in \Phi_\Sigma$, we may write $\mathsf{w}_1(q, a, q')$ for $\phi(a)$. The computation of A on words $s \in \Sigma^*$ is defined with an intermediate function weight_A, defined as follows for $q, q' \in Q$, $a \in \Sigma$, $u \in \Sigma^*$,

$$\mathsf{weight}_A(q, \varepsilon, q) = \mathbb{1} \tag{3}$$

$$\mathsf{weight}_A(q, \varepsilon, q') = \mathbb{0} \quad \text{if } q \neq q'$$

$$\mathsf{weight}_A(q, au, q') = \bigoplus_{q'' \in Q} \mathsf{w}_1(q, a, q'') \otimes \mathsf{weight}_A(q'', u, q')$$

Je crois qu'il faudrait numéroter les exemples indépendamment des définitions. Cet exemple est le premier qui donne des détails sur l'application visée. Il arrive peut-être un peu tard et est long. On pourrait introduire la motivation dans l'intro, et développer des petits exemples au fur et à mesure.

unique → similar

similar → single

reformulated this sentence

ccl to the ex

and the weight value associated by A to $s \in \Sigma^*$ is defined as follows:

$$A(s) = \bigoplus_{q,q' \in Q} \mathsf{in}(q) \otimes \mathsf{weight}_A(q, s, q') \otimes \mathsf{out}(q') \tag{4}$$

The following property will be useful to the approach on symbolic weighted parsing presented in Section 5.

▶ **Proposition 9.** *Given a swT T over Σ, Δ, $\mathbb{S}$ commutative, bounded and complete, and $\bar{\Phi}$ effective, and a swA A over Σ, $\mathbb{S}$ and $\bar{\Phi}$, there exists an effectively constructible swA $B_{T,A}$ over Δ, $\mathbb{S}$ and $\bar{\Phi}$, such that for all $t \in \Delta^*$, $B_{T,A}(t) = \bigoplus_{s \in \Sigma^*} A(s) \otimes T(s, t)$.*

Proof. Let $T = \langle Q, \mathsf{in}_T, \bar{\mathsf{w}}, \mathsf{out}_T \rangle$, where $\bar{\mathsf{w}}$ contains w_{10}, w_{01}, and w_{11}, from $Q \times Q$ into respectively Φ_Σ, Φ_Δ, and $\Phi_{\Sigma,\Delta}$, and let $A = \langle P, \mathsf{in}_A, \mathsf{w}_1, \mathsf{out}_A \rangle$ with $\mathsf{w}_1 : Q \times Q \to \Phi_\Sigma$. The state set of $B_{T,A}$ will be $Q' = P \times Q$. The entering, leaving and transition functions of $B_{T,A}$ will simulate synchronized computations of A and T, while reading an output word of Δ^*. Its state entering functions is defined for all $p \in P$, $q \in Q$ by $\mathsf{in}'(p, q) = \mathsf{in}_A(p) \otimes \mathsf{in}_T(q)$. The transition function w'_1 will roughly perform a synchronized product of transitions defined by w_1, w_{01} (T reading in output word and not an input word) and w_{11} (T reading both an input word and an output word). Moreover, w'_1 also needs to simulate transitions defined by w_{10}: T reading in input word and not an output word. Since $B_{T,A}$ will read only in the output word, such a transition corresponds to an ε-transition of swA, but swA have been defined without ε-transitions. Therefore, in order to take care of this case, we perform an on-the-fly suppression of ε-transition in the swA in construction, following the algorithm of [19]. Initially, for all $p_1, p_2 \in P$, and $q_1, q_2 \in Q$, let

$$\mathsf{w}'_1\big(\langle p_1, q_1 \rangle, \langle p_2, q_2 \rangle\big) = \mathsf{w}_1(p_1, p_2) \otimes \big[\mathsf{w}_{01}(q_1, q_2) \oplus \bigoplus_\Sigma \mathsf{w}_{11}(q_1, q_2)\big].$$

Iterate the following for all $p_1 \in P$ and $q_1, q_2 \in Q$: for all $p_2 \in P$ and $q_3 \in Q$,

$$\mathsf{w}'_1\big(\langle p_1, q_1 \rangle, \langle p_2, q_3 \rangle\big) \oplus= \bigoplus_\Sigma \mathsf{w}_{10}(q_1, q_2) \otimes \mathsf{w}'_1\big(\langle p_1, q_2 \rangle, \langle p_2, q_3 \rangle\big)$$

and $\mathsf{out}'(p_1, q_1) \oplus= \bigoplus_\Sigma \mathsf{w}_{10}(q_1, q_2) \otimes \mathsf{out}'(p_1, q_2)$ ◀

The construction time and size for $B_{T,A}$ are $O(\|T\|^3.\|A\|^2)$, where the sizes $\|T\|$ and $\|A\|$

are their number of states.

▶ **Corollary 10.** *Given a swT T over Σ, Δ, $\mathbb{S}$ commutative, bounded and complete, and $\bar{\Phi}$ effective, and $s \in \Sigma^+$, there exists an effectively constructible swA $B_{T,s}$ over Δ, $\mathbb{S}$ and $\bar{\Phi}$, such that for all $t \in \Delta^*$, $B_{T,s}(t) = T(s, t)$.*

4   SW Visibly Pushdown Automata

The model presented in this section generalizes Symbolic VPA [6] from Boolean semirings to arbitrary semiring weight domains. It will compute on nested words over infinite alphabets, associating to every such word a weight value. Nested words are able to describe structures of labeled trees, and in the context of parsing, they will be useful to represent AST.

Let Ω be a countable alphabet that we assume partitioned into three subsets Ω_i, Ω_c, Ω_r, whose elements are respectively called *internal*, *call* and *return* symbols. Let $\langle \mathbb{S}, \oplus, \mathbb{0}, \otimes, \mathbb{1} \rangle$

be a commutative and complete semiring and let $\bar{\Phi} = \langle \Phi_i, \Phi_c, \Phi_r, \Phi_{ci}, \Phi_{cc}, \Phi_{cr} \rangle$ be a label theory over $\mathbb{S}$ where Φ_i, Φ_c, Φ_r and Φ_{cx} (with $x \in \{i, c, r\}$) stand respectively for Φ_{Ω_i}, Φ_{Ω_c}, Φ_{Ω_r} and $\Phi_{\Omega_c, \Omega_x}$.

▶ **Definition 11.** *A* Symbolic Weighted Visibly Pushdown Automata *(sw-VPA) over* $\Omega = \Omega_i \uplus \Omega_c \uplus \Omega_r$, $\mathbb{S}$ *and* $\bar{\Phi}$ *is a tuple* $A = \langle Q, P, \mathsf{in}, \bar{\mathsf{w}}, \mathsf{out} \rangle$, *where* Q *is a finite set of states,* P *is a finite set of stack symbols,* $\mathsf{in} : Q \to \mathbb{S}$ *(respectively* $\mathsf{out} : Q \to \mathbb{S}$) *are functions defining the weight for entering (respectively leaving) a state, and* $\bar{\mathsf{w}}$ *is a sextuplet composed of the transition functions :* $\mathsf{w}_i : Q \times P \times Q \to \Phi_{ci}$, $\mathsf{w}_i^e : Q \times Q \to \Phi_i$, $\mathsf{w}_c : Q \times P \times Q \times P \to \Phi_{cc}$, $\mathsf{w}_c^e : Q \times P \times Q \to \Phi_c$, $\mathsf{w}_r : Q \times P \times Q \to \Phi_{cr}$, $\mathsf{w}_r^e : Q \times Q \to \Phi_r$.

Similarly as in Section 3, we extend the above transition functions as follows for all $q, q' \in Q$, $p \in P$, $a \in \Omega_i$, $c \in \Omega_c$, $r \in \Omega_r$, overloading their names:

$$
\begin{array}{lll}
\mathsf{w}_i : Q \times \Omega_c \times P \times \Omega_i \times Q \to \mathbb{S} & \mathsf{w}_i(q, c, p, a, q') = \eta_{ci}(c, a) & \text{where } \eta_{ci} = \mathsf{w}_i(q, p, q'), \\
\mathsf{w}_i^e : Q \times \Omega_i \times Q \to \mathbb{S} & \mathsf{w}_i^e(q, a, q') = \phi_i(a) & \text{where } \phi_i = \mathsf{w}_i^e(q, q'). \\
\mathsf{w}_c : Q \times \Omega_c \times P \times \Omega_c \times P \times Q \to \mathbb{S} & \mathsf{w}_c(q, c, p, c', p', q') = \eta_{cc}(c, c') & \text{where } \eta_{cc} = \mathsf{w}_c(q, p, p', q'), \\
\mathsf{w}_c^e : Q \times \Omega_c \times P \times Q \to \mathbb{S} & \mathsf{w}_c^e(q, c, p, q') = \phi_c(c) & \text{where } \phi_c = \mathsf{w}_c^e(q, p, q'). \\
\mathsf{w}_r : Q \times \Omega_c \times P \times \Omega_r \times Q \to \mathbb{S} & \mathsf{w}_r(q, c, p, r, q') = \eta_{cr}(c, r) & \text{where } \eta_{cr} = \mathsf{w}_r(q, p, q'), \\
\mathsf{w}_r^e : Q \times \Omega_r \times Q \to \mathbb{S} & \mathsf{w}_r^e(q, r, q') = \phi_r(r) & \text{where } \phi_r = \mathsf{w}_r^e(q, q').
\end{array}
$$

The intuition is the following for the above transitions. w_i^e, w_c^e, and w_r^e describe the cases where the stack is empty. w_i and w_i^e both read an input internal symbol a and change state from q to q', without changing the stack. Moreover, w_i reads a pair made of $c \in \Omega_c$ and $p \in P$ on the top of the stack (c is compared to a by the weight function $\eta_{ci} \in \Phi_{ci}$). w_c and w_c^e read the input call symbol c', push it to the stack along with p', and change state from q to to q'. Moreover, w_c reads c and p at the top of the stack (c is compared to c'). w_r and w_r^e read the input return symbol r, and change state from q to to q'. Moreover, w_r reads and pop from stack a pair made of c and p, (c is compared to r).

Formally, the transitions of the automaton A are defined in term of an intermediate function weight_A, like in Section 3. A configuration, denoted by $q[\gamma]$, is here composed of a state $q \in Q$ and a stack content $\gamma \in \Gamma^*$, where $\Gamma = \Omega_c \times P$. Hence, weight_A is a function from $[Q \times \Gamma^*] \times \Omega^* \times [Q \times \Gamma^*]$ into $\mathbb{S}$. The empty stack is denoted by $\perp$, and the upmost symbol is the last pushed content. The following functions illustrate each of the possible cases, being : reading $a \in \Omega_i$, or $c \in \Omega_c$, or $r \in \Omega_r$ for each possible state of the stack (empty or not), to add to $u \in \Omega^*$.

$$\mathsf{weight}_A\big(q[\perp], \varepsilon, q'[\perp]\big) = \mathbb{1} \text{ if } q = q' \text{ and } \mathbb{0} \text{ otherwise} \tag{5}$$

$$\mathsf{weight}_A\big(q \begin{bmatrix} \langle c, p \rangle \\ \gamma \end{bmatrix}, a\,u, q'[\gamma']\big) = \bigoplus_{q'' \in Q} \mathsf{w}_i(q, c, p, a, q'') \otimes \mathsf{weight}_A\big(q'' \begin{bmatrix} \langle c, p \rangle \\ \gamma \end{bmatrix}, u, q'[\gamma']\big)$$

$$\mathsf{weight}_A\big(q[\perp], a\,u, q'[\gamma']\big) = \bigoplus_{q'' \in Q} \mathsf{w}_i^e(q, a, q'') \otimes \mathsf{weight}_A\big(q''[\perp], u, q'[\gamma']\big)$$

$$\mathsf{weight}_A\big(q \begin{bmatrix} \langle c, p \rangle \\ \gamma \end{bmatrix}, c'\,u, q'[\gamma']\big) = \bigoplus_{\substack{q'' \in Q \\ p' \in P}} \mathsf{w}_c(q, c, p, c', p', q'') \otimes \mathsf{weight}_A\big(q'' \begin{bmatrix} \langle c', p' \rangle \\ \langle c, p \rangle \\ \gamma \end{bmatrix}, u, q'[\gamma']\big)$$

$$\mathsf{weight}_A\big(q[\perp], c\,u, q'[\gamma']\big) = \bigoplus_{\substack{q'' \in Q \\ p \in P}} \mathsf{w}_c^e(q, c, p, q'') \otimes \mathsf{weight}_A\big(q''[\langle c, p \rangle], u, q'[\gamma']\big)$$

$$\mathsf{weight}_A\Big(q\begin{bmatrix} \langle c,p\rangle \\ \gamma \end{bmatrix}, r\,u, q'[\gamma']\Big) = \bigoplus_{q''\in Q} \mathsf{w_r}\big(q,c,p,r,q''\big) \otimes \mathsf{weight}_A\big(q''[\gamma], u, q'[\gamma']\big) \tag*{342}$$

$$\mathsf{weight}_A\big(q[\bot], r\,u, q'[\gamma']\big) = \bigoplus_{q''\in Q} \mathsf{w_r^e}(q,r,q'') \otimes \mathsf{weight}_A\big(q''[\bot], u, q'[\gamma']\big) \tag*{343}$$

344

`c p to <c, p>`   345

346 The weight associated by A to $s \in \Omega^*$ is defined according to empty stack semantics:

$$A(s) = \bigoplus_{q,q'\in Q} \mathsf{in}(q) \otimes \mathsf{weight}_A\big(q[\bot], s, q'[\bot]\big) \otimes \mathsf{out}(q'). \tag{6}$$

347

`todo example VPA`   348 ▶ **Example 12.** structured words with timed symbols... intro language of music notation?
349 (markup = time division, leaves = events etc)

350 Every swA $A = \langle Q, \mathsf{in}, \mathsf{w_1}, \mathsf{out}\rangle$, over Σ, $\mathbb{S}$ and $\bar{\bar{\Phi}}$ is a particular case of sw-VPA $\langle Q, \emptyset, \mathsf{in}, \bar{\mathsf{w}}, \mathsf{out}\rangle$
351 over Ω, $\mathbb{S}$ and $\bar{\bar{\Phi}}$ with $\Omega_\mathsf{i} = \Sigma$ and $\Omega_\mathsf{c} = \Omega_\mathsf{r} = \emptyset$, and computing with an always empty stack:
352 $\mathsf{w_i^e} = \mathsf{w_1}$ and all the other functions of $\bar{\mathsf{w}}$ are the constant $\mathbb{0}$.

353 Like VPA and symbolic VPA, the class of sw-VPA is closed under the binary operators of
354 the underlying semiring.

355 ▶ **Proposition 13.** *Let A_1 and A_2 be two sw-VPA over the same Ω, $\mathbb{S}$ and $\bar{\bar{\Phi}}$. There*
356 *exists two effectively constructible sw-VPA $A_1 \oplus A_2$ and $A_1 \otimes A_2$, such that for all $s \in \Omega^*$,*
357 *$(A_1 \oplus A_2)(s) = A_1(s) \oplus A_2(s)$ and $(A_1 \otimes A_2)(s) = A_1(s) \otimes A_2(s)$.*

358 **Proof.** The construction is essentially the same as in the case of the Boolean semiring [6]. ◀

`total?`   359 Let us assume that the semiring $\mathbb{S}$ is commutative, bounded, and complete, and that $\bar{\bar{\Phi}}$ is an
360 effective label theory. We propose a Dijkstra algorithm computing, for a sw-VPA A over Ω,
361 $\mathbb{S}$ and $\bar{\bar{\Phi}}$, the minimal weight for a word in Ω^*. We distinguish two cases : when the stack is
`introduced 2 cases for b`   362 empty, and when it is not. In the case of an empty stack, let $b_\bot : Q \times Q \to \mathbb{S}$ be such that :

$$b_\bot(q,q') = \bigoplus_{s\in\Omega^*} \mathsf{weight}_A\big(q[\bot], s, q'[\bot]\big). \tag{7}$$

363

364 Since $\mathbb{S}$ is complete, the infinite sum in (7) is well defined, and, providing that $\mathbb{S}$ is total,
365 it is the minimum in Ω^*, *wrt* $\leq_\oplus$, of the fonction $s \mapsto \mathsf{weight}_A(q[\sigma], s, q'[\sigma])$. The term
366 $q[\bot], s, q'[\bot]$ of this sum is the central expression in the definition (6) of $A(s_0)$, for the
`so ?`   367 minimum s_0 of the function weight_A.

`b_⊤ : mot bien par-enthèsé c/r`   368 If the stack is not empty, let $\top$ be a fresh stack symbol which does not belong to Γ, and let
369 $b_\top : Q \times P \times Q \to \Phi_\mathsf{c}$ be such that, for every two states $q, q' \in Q$ and stack symbol $p \in P$:

$$b_\top(q,p,q') : c \mapsto \bigoplus_{s\in\Omega^*} \mathsf{weight}_A\Big(q\begin{bmatrix}\langle c,p\rangle \\ \top\end{bmatrix}, s, q'\begin{bmatrix}\langle c,p\rangle \\ \top\end{bmatrix}\Big) \tag{8}$$

370

371 Intuitively, the function defined in (8) associates to $c \in \Omega_\mathsf{c}$ the minimum weight of a
372 computation of A starting in state q with a stack $\langle c,p\rangle \cdot \gamma \in \Gamma^+$ and ending in state q' with
373 the same stack, such that the computation can not pop the pair made of c and p at the top
374 of this stack, but may only read these symbols. Moreover, A may push another pair $\langle c',p'\rangle$
375 on the top of $\langle c,p\rangle \cdot \gamma$, following the third case of in the definition (5) of weight_A, and may
376 pop $\langle c',p'\rangle$ later, following the fifth case of (5) (return symbol).
377   Algorithm 1 constructs iteratively markings $d_\bot : Q \times Q \to \mathbb{S}$ and $d_\top : Q \times P \times Q \to \Phi_\mathsf{c}$
378 that converges eventually to $b_\top$ and $b_\bot$.

■ **Algorithm 1** Best search for sw-VPA

initially let $\mathcal{Q} = (Q \times Q) \cup (Q \times P \times Q)$, and let $d_\perp(q_1, q_2) = d_\top(q_1, p, q_2) = \mathbb{1}$ if $q_1 = q_2$ and $d_\perp(q_1, q_2) = d_\top(q_1, p, q_2) = \mathbb{0}$ otherwise

while $\mathcal{Q} \neq \emptyset$ **do**

  extract $\langle q_1, q_2 \rangle$ or $\langle q_1, p, q_2 \rangle$ from $\mathcal{Q}$ such that $d_\perp(q_1, q_2)$, resp.
  $\bigoplus_{c \in \Omega_c} d_\top(q_1, p, q_2)(c)$, is minimal in $\mathbb{S}$ *wrt* $\leq_\oplus$

  update $d_\perp$ with $\langle q_1, q_2 \rangle$ or $d_\top$ with $\langle q_1, p, q_2 \rangle$ (Figure 3).

For all $q_0, q_3 \in Q$,

$$d_\top(q_1, p, q_3) \quad \oplus= \quad d_\top(q_1, p, q_2) \otimes \bigoplus_{\Omega_i} \mathsf{w_i}(q_2, p, q_3)$$

$$d_\perp(q_1, p, q_3) \quad \oplus= \quad d_\perp(q_1, q_2) \otimes \bigoplus_{\Omega_i} \mathsf{w_i^e}(q_2, q_3)$$

$$d_\top(q_0, p, q_3) \quad \oplus= \quad \bigoplus_{\Omega_c}^2 \big[\big(\mathsf{w_c}(q_0, p, p', q_1) \otimes_2 d_\top(q_1, p', q_2) \big) \otimes_2 \bigoplus_{\Omega_r} \mathsf{w_r}(q_2, p', q_3) \big]$$

$$d_\perp(q_0, q_3) \quad \oplus= \quad \bigoplus_{\Omega_c} \big(\mathsf{w_c^e}(q_0, p, q_1) \otimes d_\top(q_1, p, q_2) \otimes \bigoplus_{\Omega_r} \mathsf{w_r}(q_2, p, q_3) \big)$$

$$d_\perp(q_1, q_3) \quad \oplus= \quad d_\perp(q_1, q_2) \otimes \bigoplus_{\Omega_r} \mathsf{w_r^e}(q_2, q_3)$$

$$d_\top(q_1, p, q_3) \quad \oplus= \quad d_\top(q_1, p, q_2) \otimes d_\top(q_2, p, q_3), \text{if } \langle q_2, \top, q_3 \rangle \notin P$$

$$d_\perp(q_1, q_3) \quad \oplus= \quad d_\perp(q_1, q_2) \otimes d_\perp(q_2, q_3), \text{if } \langle q_2, \bot, q_3 \rangle \notin P$$

■ **Figure 3** Update $d_\perp$ with $\langle q_1, q_2 \rangle$ or $d_\top$ with $\langle q_1, p, q_2 \rangle$.

The infinite sums in the updates of d in Algorithm 1, Figure 3 are well defined since $\mathbb{S}$ is complete. ** effectively computable by hypothesis that the label theory is effective** The algorithm performs $2.|Q|^2$ iterations until P is empty, and each iteration has a time complexity $O(|Q|^2.|P|)$. That gives a time complexity $O(|Q|^4.|P|)$. It can be reduced by implementing P as a priority queue, prioritized by the value returned by d.

The correctness of Algorithm 1 is ensured by the invariant expressed in the following lemma.

▶ **Lemma 14.** *For all* $\langle q_1, q_2 \rangle \notin \mathcal{Q}$, $d_\perp(q_1, q_2) = b_\perp(q_1, q_2)/$

The proof is by contradiction, assuming a counter-example minimal in the length of the witness word.

▶ **Lemma 15.** *For all* $\langle q_1, p, q_2 \rangle \notin \mathcal{Q}$, $d_\top(q_1, p, q_2) = b_\top(q_1, p, q_2)$,

For computing the minimal weight of a computation of A, we use the fact that, at the termination of Algorithm 1, $\bigoplus_{s \in \Omega^*} A(s) = \bigoplus_{q,q' \in Q} \mathsf{in}(q) \otimes d_\perp(q, q') \otimes \mathsf{out}(q')$.

In order to obtain effectively a witness (word of Ω^* with a computation of A of minimal weight), we require the additional property of convexity of weight functions.

▶ **Proposition 16.** *For a sw-VPA A over Ω, $\mathbb{S}$ commutative, bounded, total and complete, and $\bar{\Phi}$ effective, one can construct in PTIME a word $t \in \Omega^*$ such that $A(t)$ is minimal wrt the natural ordering for $\mathbb{S}$.*

5   Symbolic Weighted Parsing

Let us now apply the models and results of the previous sections to the problem of parsing over infinite alphabet. Let Σ be a countable input alphabet, and $\Omega = \Omega_i \uplus \Omega_c \uplus \Omega_r$ be a countable output alphabet. Let $\langle \mathbb{S}, \oplus, \mathbb{0}, \otimes, \mathbb{1} \rangle$ be a commutative, bounded, and complete semiring and let $\bar{\Phi}$ be an effective label theory over $\mathbb{S}$, containing Φ_Σ, Φ_{Σ, Ω_i}, as well as Φ_i, Φ_c, Φ_r, Φ_{cr} (following the notations of Section 4). We assume given the following input:

- a swT T over Σ, Ω_i, $\mathbb{S}$, and $\bar{\Phi}$, defining a measure $T : \Sigma^* \times \Omega_i^* \to \mathbb{S}$,
- a sw-VPA A over Ω, $\mathbb{S}$, and $\bar{\Phi}$, defining a measure $A : \Omega^* \to \mathbb{S}$,
- an input word $s \in \Sigma^*$.

For all $s \in \Sigma^*$ and $t \in \Omega^*$, let $d(s,t) = T\bigl(s, t|_{\Omega_i}\bigr)$, where $t|_{\Omega_i} \in \Omega_i^*$ is the projection of t onto Ω_i, obtained from t by removing all symbols in $\Omega \setminus \Omega_i$. *Symbolic weighted parsing* is the problem, given the above input, to find $t \in \Omega^*$ minimizing $d(s,t) \otimes A(t)$ *wrt* $\leq_\oplus$, *i.e.* s.t.

$$d(s,t) \otimes A(t) = \bigoplus_{t' \in \mathcal{T}(\Omega)} d(s,t') \otimes A(t') \tag{9}$$

Following the terminology of [21], sw-parsing is the problem of computing the distance (9) between the input s and the output weighted language of A, and returning a witness t. Every labeled tree t can be linearized into a nested word $\mathsf{lin}(t) \in \Omega^*$, assuming *e.g.* that Ω_i contain the symbols labelling the leaves (symbols of rank 0) and Ω_c and Ω_r contain respectively one left and right parenthesis $\langle_b$ and $_b \rangle$ for each symbol b labelling inner nodes (symbols of rank > 0). With this representation, the projection $\mathsf{lin}(t)|_{\Omega_i}$ is then the sequence of leaves of t, enumerated in a *dfs*-traversal. We show in Appendix A how to convert a (sw) tree automaton A into a sw-VPA computing $A(\mathsf{lin}(t))$ for every tree t. That also holds, for the set of ASTs of a weighted CF-grammar. Therefore, sw-parsing generalizes the problem of searching, the best derivation of a weighted CF-grammar that yields a given input, sometimes referred as *weighted parsing*, see *e.g.* [13] and [23] for a more general weighted parsing framework. The latter indeed corresponds to the particular case where the alphabet is finite, T computes identity and A is obtained from the weighted CF grammar.

▶ **Proposition 17.** *The problem of Symbolic Weighted parsing can be solved in PTIME in the size of the input swT T, sw-VPA A and input word s, and the computation time of the functions of the label theory.*

Proof. (sketch) We follow a *Bar-Hillel* construction, also called parsing by intersection. We first extend the swT T over Σ, Ω_i, $\mathbb{S}$, and $\bar{\Phi}$, into a swT T' over Σ and Ω (and the same semiring and label theory), such that for all $s \in \Sigma^*$, and $u \in \Omega^*$, $T'(s, u) = T(s, u|_{\Omega_i})$. The transducer T' simply skips every symbol $b \in \Omega \setminus \Omega_i$, by the addition to the transition of T, of new transitions of the form $\mathsf{w}_{01}(q, \varepsilon, b, q')$. Then, given an input word $s \in \Sigma^*$, using Corolary 10, we compute the swA $B_{T',s}$, such that for all $t \in \Omega^*$, $B_{T',s}(t) = d(s,t)$.
Next, we compute the sw-VPA $B_{T',s} \otimes A$, using Proposition 13. It remains to compute a best nested-word $w \in \Omega^*$ using the best-search procedure of Proposition 16. ◀

Conclusion

We have introduced weighted language models (SW transducers and visibly pushdown automata) computing over infinite alphabets, and applied them to the problem of parsing with infinitely many possible input symbols (typically timed events). This approach extends conventional parsing and weighted parsing by computing a derivation tree modulo a generic

distance between words, defined by a SW transducer given in input. This enables to consider finer word relationships than strict equality, opening possibilities of quantitative analysis via this method.

Ongoing and future work include

TODO future work

– The study of other theoretical properties of SW models, such as the extension of the best search algorithm from 1-best to n-best [17], and to k-*closed* semirings [20] (instead of *bounded*, which corresponds to 0-*closed*).

– ...there is room to improve the complexity bounds for the algorithms ... modular approach with oracles ...

– present here an offline algorithm for best search, semi-online implementation for AMT (bar-by-bar approach) with an on-the-fly automata construction.

509 ## A   Nested-Words and Parse-Trees

510 The hierarchical structure of nested-words, defined with the *call* and *return* markup symbols
511 suggest a correspondence with trees. The lifting of this correspondence to languages, of tree
512 automata and VPA, has been discussed in [1], and [4] for the weighted case. In this section,
513 we describe a correspondence between the symbolic-weighted extensions of tree automata
514 and VPA.

515   Let Ω be a countable ranked alphabet, such that every symbol $a \in \Omega$ has a rank
516 $\mathsf{rk}(a) \in [0..M]$ where M is a fixed natural number. We denote by Ω_k the subset of all symbols
517 a of Ω with $\mathsf{rk}(a) = k$, where $0 \leq k \leq M$, and $\Omega_{>0} = \Omega \setminus \Omega_0$. The free Ω-algebra of finite,
518 ordered, Ω-labeled trees is denoted by $\mathcal{T}(\Omega)$. It is the smallest set such that $\Omega_0 \subset \mathcal{T}(\Omega)$
519 and for all $1 \leq k \leq M$, all $a \in \Omega_k$, and all $t_1, \ldots, t_k \in \mathcal{T}(\Omega)$, $a(t_1, \ldots, t_k) \in \mathcal{T}(\Omega)$. Let us
520 assume a commutative semiring $\mathbb{S}$ and a label theory $\bar{\Phi}$ over $\mathbb{S}$ containing one set Φ_{Ω_k} for
521 each $k \in [0..M]$.

522 ▶ **Definition 18.** *A symbolic-weighted tree automaton (swTA) over Ω, $\mathbb{S}$, and $\bar{\Phi}$ is a triplet*
523 $A = \langle Q, \mathsf{in}, \bar{\mathsf{w}} \rangle$ *where Q is a finite set of states,* $\mathsf{in} : Q \to \Phi_\Omega$ *is the starting weight function,*
524 *and $\bar{\mathsf{w}}$ is a tuplet of transition functions containing, for each $k \in [0..M]$, the functions*
525 $\mathsf{w}_k : Q \times Q^k \to \Phi_{\Omega_{>0},\Omega_k}$ *and* $\mathsf{w}_k^{\mathsf{e}} : Q \times Q^k \to \Phi_{\Omega_k}$.

526 We define a transition function $\mathsf{w} : Q \times (\Omega_{>0} \cup \{\varepsilon\}) \times \Omega \times \bigcup_{k=0}^{M} Q^k \to \mathbb{S}$ by:

527
$$
\begin{aligned}
\mathsf{w}(q_0, a, b, q_1 \ldots q_k) &= \eta(a, b) && \text{where } \eta = \mathsf{w}_k(q_0, q_1 \ldots q_k) \\
\mathsf{w}(q_0, \varepsilon, b, q_1 \ldots q_k) &= \phi(b) && \text{where } \phi = \mathsf{w}_k^{\mathsf{e}}(q_0, q_1 \ldots q_k).
\end{aligned}
$$

528 where $q_1 \ldots q_k$ is ε if $k = 0$. The first case deals with a strict subtree, with a parent node
529 labeled by a, and the second case is for a root tree.
530 Every swTA defines a mapping from trees of $\mathcal{T}(\Omega)$ into $\mathbb{S}$, based on the following intermediate
531 function $\mathsf{weight}_A : Q \times (\Omega \cup \{\varepsilon\}) \times \mathcal{T}(\Omega) \to \mathbb{S}$

532
$$
\mathsf{weight}_A(q_0, a, t) = \bigoplus_{q_1 \ldots q_k \in Q^k} \mathsf{w}(q_0, a, b, q_1 \ldots q_k) \otimes \bigotimes_{i=1}^{k} \mathsf{weight}_A(q_i, b, t_i) \tag{10}
$$

533 where $q_0 \in Q$, $a \in \Omega_{>0} \cup \{\varepsilon\}$ and $t = b(t_1, \ldots, t_k) \in \mathcal{T}(\Omega)$, $0 \leq k \leq M$.

534 Finally, the weight associated by A to $t \in \mathcal{T}(\Omega)$ is

535
$$
A(t) = \bigoplus_{q \in Q} \mathsf{in}(q) \otimes \mathsf{weight}_A(q, \varepsilon, t) \tag{11}
$$

536 Intuitively, $\mathsf{w}(q_0, a, b, q_1 \ldots q_k)$ can be seen as the weight of a production rule $q_0 \to b(q_1, \ldots, q_k)$
537 of a regular tree grammar [5], that replaces the non-terminal symbol q_0 by $b(q_1, \ldots, q_k)$,
538 provided that the parent of q_0 is labeled by a (or q_0 is the root node if $a = \varepsilon$). The
539 above production rule can also be seen as a rule of a weighted CF grammar, of the form
540 $[a, b] \, q_0 := q_1 \ldots q_k$ if $k > 0$, and $[a] \, q_0 := b$ if $k = 0$. In the first case, b is a label of the rule,
541 and in the second case, it is a terminal symbol. And in both cases, a is a constraint on the
542 label of rule applied on the parent node in the derivation tree. This features of observing
543 the parent's label are useful in the case of infinite alphabet, where it is not possible to
544 memorize a label with the states. The weight of a labeled derivation tree t of the weighted
545 CF grammar associated to A as above, is $\mathsf{weight}_A(q, t)$, when q is the start non-terminal. We
546 shall now establish a correspondence between such derivation tree t and some word describing
547 a linearization of t, in a way that $\mathsf{weight}_A(q, t)$ can be computed by a sw-VPA.

Let $\hat{\Omega}$ be the countable (unranked) alphabet obtained from Ω by: $\hat{\Omega} = \Omega_i \uplus \Omega_c \uplus \Omega_r$, with $\Omega_i = \Omega_0$, $\Omega_c = \{ \langle_a | \ a \in \Omega_{>0} \}$, $\Omega_r = \{ \ _a\rangle \mid a \in \Omega_{>0} \}$.
We associate to $\hat{\Omega}$ a label theory $\hat{\Phi}$ like in Section 4, and we define a linearization of trees of $\mathcal{T}(\Omega)$ into words of $\hat{\Omega}^*$ as follows:

$\mathsf{lin}(a) = a$ for all $a \in \Omega_0$,

$\mathsf{lin}\big(b(t_1, \ldots, t_k)\big) = \langle_b \mathsf{lin}(t_1) \ldots \mathsf{lin}(t_k) \ _b\rangle$ when $b \in \Omega_k$ for $1 \leq k \leq M$.

▶ **Proposition 19.** *For all swTA A over Ω, $\mathbb{S}$ commutative, and $\bar{\Phi}$, there exists an effectively constructible sw-VPA A' over $\hat{\Omega}$, $\mathbb{S}$ and $\hat{\Phi}$ such that for all $t \in \mathcal{T}(\Omega)$, $A'\big(\mathsf{lin}(t)\big) = A(t)$.*

Proof. Let $A = \langle Q, \mathsf{in}, \bar{w} \rangle$ where $\bar{w}$ is presented as above by a function We build $A' = \langle Q', P', \mathsf{in}', \bar{w}', \mathsf{out}' \rangle$, where $Q' = \bigcup_{k=0}^{M} Q^k$ is the set of sequences of state symbols of A, of length at most M, including the empty sequence denoted by ε, and where $P' = Q'$ and $\bar{w}$ is defined by:
$$
\begin{aligned}
\mathsf{w_i}(q_0 \, \bar{u}, \langle_c, \bar{p}, a, \bar{u}) &= \mathsf{w}(q_0, c, a, \varepsilon) & \text{for all } c \in \Omega_{>0}, a \in \Omega_0 \\
\mathsf{w_i^e}(q_0 \, \bar{u}, a, \bar{u}) &= \mathsf{w}(q_0, \varepsilon, a, \varepsilon) & \text{for all } a \in \Omega_0 \\
\mathsf{w_c}(q_0 \, \bar{u}, \langle_c, \bar{p}, \langle_d, \bar{u}, \bar{q}) &= \mathsf{w}(q_0, c, d, \bar{q}) & \text{for all } c, d \in \Omega_{>0} \\
\mathsf{w_c^e}(q_0 \, \bar{u}, \langle_c, \bar{u}, \bar{q}) &= \mathsf{w}(q_0, \varepsilon, c, \bar{q}) & \text{for all } c \in \Omega_{>0} \\
\mathsf{w_r}(\varepsilon, \langle_c, \bar{p}, \ _c\rangle, \bar{p}) &= \mathbb{1} & \text{for all } c \in \Omega_{>0} \\
\mathsf{w_r^e}(\bar{u}, \ _c\rangle, \bar{q}) &= \mathbb{0} & \text{for all } c \in \Omega_{>0}
\end{aligned}
$$

All cases not matched by one of the above equations have a weight $\mathbb{0}$, for instance $\mathsf{w_r}(\bar{u}, \langle_c, \bar{p}, \ _d\rangle, \bar{q}) = \mathbb{0}$ if $c \neq d$ or $\bar{u} \neq \varepsilon$ or $\bar{q} \neq \bar{p}$. ◀
